

Greenhouse Gasses Emissions in World's Economy - Report

Aleksandra Dacko

Introduction

This report was prepared based on the EDGAR GHG Emissions database coming from 2024 'GHG emissions of all world countries' Publication (Crippa and Pekar 2024) ([report link](#))

All data manipulations, visualizations, and insights were integrated and documented within an R Markdown file. R Markdown allows for seamless integration of R code, markdown and LaTeX languages to ensure reproducibility, clarity, and transparency in how the analysis was conducted.

- **Data Manipulations:** The raw data was processed using various R functions, including filtering, grouping, and summarizing, to derive year to year percentage change and arithmetic mean. Libraries like `dplyr` and `tidyr` were used to clean, transform, and aggregate the data where necessary.
- **Plotting:** Visualizations were created using the `ggplot2` and `treemapify` package, which allowed for custom-designed plots to effectively communicate trends and relationships present in data.

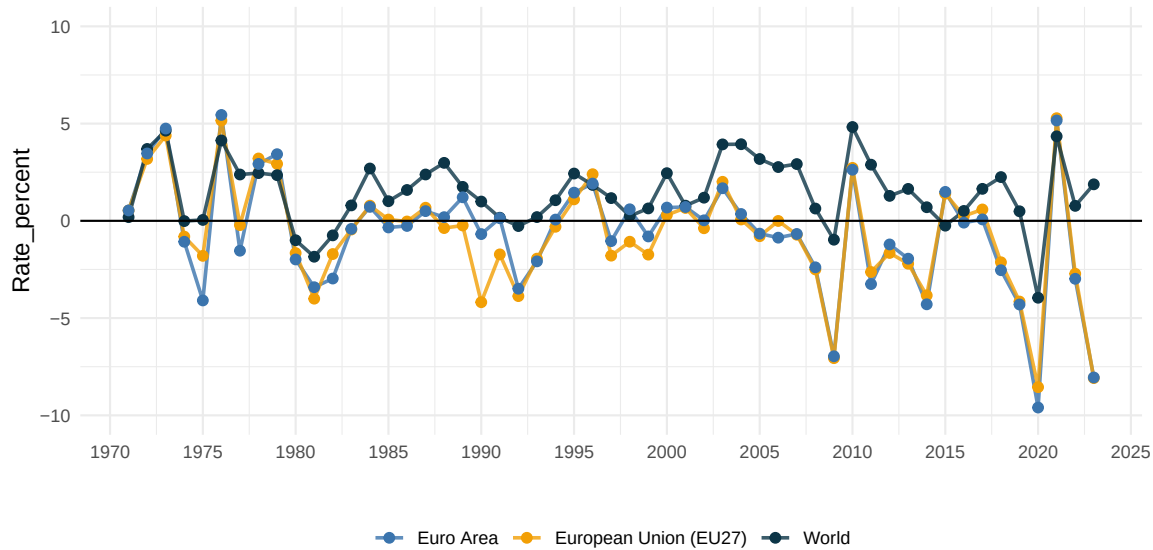

Insights report

Evolution of GHG growth in the euro area, European Union (EU27) and worldwide

- In the European Union (EU27) and Euro Area, there was a noticeable 7.5% (or 261 Mt CO_{2-eq}) decrease in total GHG emissions in 2023 compared to 2022, continuing the EU27 decreasing trend.
- From 1970 to 2023 the EU27 and Euro Area countries showed steady decline in GHG emissions with 15% compounded growth rate.
- In 2023, all EU27 countries except Croatia and Cyprus experienced a decrease in their emission levels compared to the previous year. In terms of contribution to the EU27's GHG emissions in 2023, Germany remained the largest emitter, followed by France, Italy, Poland and Spain.

Greenhouse Gasses Emission – Year to year growth rate

% change of Total GHG emission

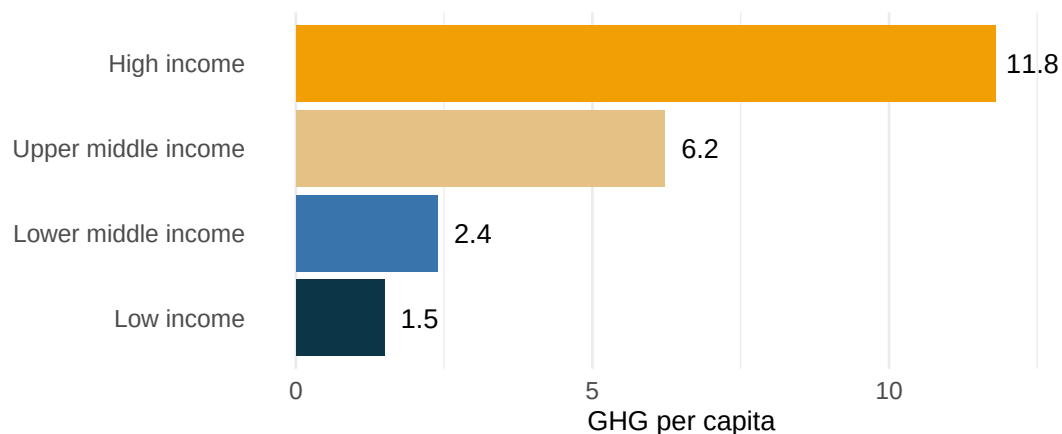

Comparison of countries' GHG emissions per capita aggregated according to the World Bank income groups;

- On average high-income countries emit around 11.8 Mt CO₂ per capita whereas low-income countries emits almost 8 times less t Co₂-eq with average of 1.5 Mt CO₂ per capita which highlights disproportional emissions responsibility of wealthier nations.

Greenhouse Gasses Emission per capita – Income groups comaparison in 2023

Tonnes of CO₂ – equivalent per person

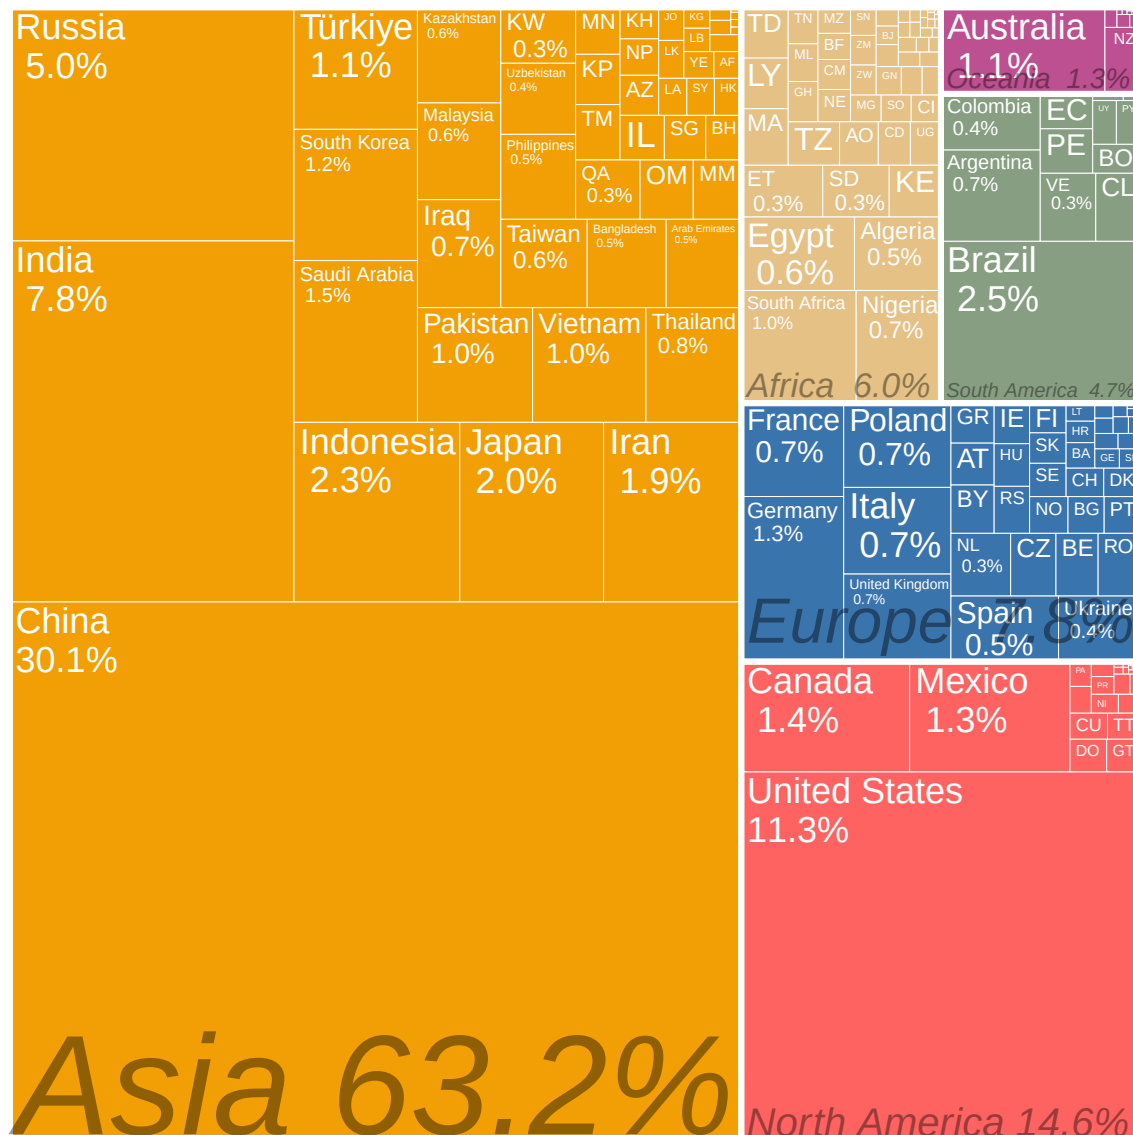

Note.(1) Individual countries were classified based on the latest clasification provided by World Bank (<https://datatopics.worldbank.org/world-development-indicators/the-world-by-income-and-region.html>)
(2) biubfu

Contribution of individual country and continent GHG emissions to total world GHG emissions.

- China, the United States, India, Russia and Brazil were the world's largest GHG emitters in 2023. Together they account for 49.8% of global population and 62.7% of global GHG emissions.
- Asia is responsible for the largest share of emissions, mainly due to rapid industrialization in countries like China. The second
- In 2023, all EU27 countries except Croatia and Cyprus experienced a decrease in their emission levels compared to the previous year. In terms of contribution to the EU27's GHG emissions in 2023, Germany remained the largest emitter, followed by France, Italy, Poland and Spain.
